

BANK ACCOUNT-OOPS CASE STUDY

A XYZ banks wants to automate the basic functionality of one branch. The features that need to be automated are:

1. Over the counter activities:
2. Account lifecycle:
3. Interest Calculation:
4. End of day report for daily transactions

The bank has different type of accounts:

1. Savings Account
2. Salary Account
3. Current Account
4. Loan Account

A savings account is typically used by an individual for personal usage and it is necessary for the account to have an average minimum balance of 10000 rs. across the quarter.

A Salary account is exactly similar to a savings account except that it has a time limit in which at least one transaction should have taken place. If no transactions happen on a salary account for two months, the account is frozen and the account holder is notified.

A current account does not have any such facilities or restrictions. The current account allows the customer to have an overdraft facility, where the customer will have a maximum limit set that he can withdraw over the current balance.

A loan account can keep track of the amount of loan repaid by a specific customer who has taken a loan from the bank. It acts as a standard savings account, but has an initial balance of negative (loan amount), and interest is also calculated accordingly.

Note: Define the hierarchy first, before writing the code
We can have array of account type with dynamic polymorphism concept

We can do a menu driven program with options like:

1. Open account of specific type
2. Login
1. Deposit
2. Withdraw
3. CheckBalance
4. DailyTrascation
5. CalculateInterest
3. Close Account
